Computer Enthusiast

I have been fascinated by computers since I was around ten years old. I never liked using technology without understanding how it worked underneath, so I kept digging deeper. That curiosity eventually led me to study computer engineering, where I now get to explore the inner workings of systems that once felt mysterious.
I started learning programming around 2016 with C through Alison courses. Around the same time, I began freelancing on Fiverr where I mainly worked on graphic design projects and was able to work with more than twenty clients. Even though the work was mostly design-focused, it was my first exposure to working with real clients, understanding requirements, and delivering work under deadlines.
During 2017, I started learning Java using Head First Java and experimented with Android development. My coding paused for a while during my A/L years, but as soon as I finished I jumped straight back into it through Harvard's CS50x. Since then I have continued exploring different areas of computing through courses and personal projects.
One thing about me is that I find it difficult to leave a problem unsolved. When something breaks, I tend to keep digging until I understand exactly why it broke. Many nights have gone into debugging deployment failures, tracing strange bugs, or analysing logs and data until the root cause becomes clear.

Research Ventures

Alongside engineering work, I have also been involved in academic research for several years and have co-authored multiple accepted abstracts and papers.

Recently, my own abstract was accepted for an **oral presentation at the BMES Conference 2025**. This meant a lot to me because the project took nearly two years of continuous work, experimentation, and iteration.

Research has taught me patience and discipline — especially the importance of carefully investigating a problem before claiming to understand it.

Entrepreneurial Ventures

Over the past four years, I have built and deployed cloud-based software solutions for more than ten clients while continuing my university studies.

These projects ranged from full web systems to backend services and mobile applications. I have developed and deployed applications, managed servers, handled real client requirements, and maintained systems once users started relying on them.

One of my most rewarding experiences was building systems from scratch — including a complete point-of-sale platform — and seeing them used in real environments.
Balancing client projects with coursework and exams was challenging, especially when urgent requests came during academic deadlines. However, it taught me how to deliver reliable software under pressure and manage real-world expectations.
